

Counting up to symmetry

Peter Rowlett

1 Symmetries as permutations

Recall that $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 3 & 1 \end{pmatrix}$ represents a function that maps

$$\sigma(1) = 2$$

$$\sigma(2) = 4$$

$$\sigma(3) = 3$$

$$\sigma(4) = 1.$$

We can write this as a product of disjoint cycles.

In general:

- $(\dots xy \dots)$ means x shifts to y ;
- $(x \dots y)$ means y shifts to x .

For example

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 3 & 1 \end{pmatrix} = (124)(3);$$

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 4 & 3 & 2 & 1 \end{pmatrix} = (14)(23);$$

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 1 \end{pmatrix} = (1234);$$

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 2 & 3 & 4 \end{pmatrix} = (1)(2)(3)(4).$$

We can write the symmetries of a square as permutations. Consider the square

First we consider the rotations.

$$e: \begin{array}{cc} (1) & (2) \\ (4) & (3) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 2 & 3 & 4 \end{pmatrix} = (1)(2)(3)(4).$$

$$r: \begin{array}{cc} (4) & (1) \\ (3) & (2) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 4 & 1 & 2 & 3 \end{pmatrix} = (1234).$$

$$r^2: \begin{array}{cc} (3) & (4) \\ (2) & (1) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 4 & 1 & 2 \end{pmatrix} = (13)(24).$$

$$r^3: \begin{array}{cc} (2) & (3) \\ (1) & (4) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 1 \end{pmatrix} = (1234).$$

Next we consider the reflections, labelled as follows.

$$\rho_1: \begin{array}{cc} (4) & (3) \\ (1) & (2) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 4 & 3 & 2 & 1 \end{pmatrix} = (14)(23).$$

$$\rho_2: \begin{array}{cc} (3) & (2) \\ (4) & (1) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 2 & 1 & 4 \end{pmatrix} = (13)(2)(4).$$

$$\rho_3: \begin{array}{cc} (3) & (2) \\ (4) & (1) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 4 & 3 \end{pmatrix} = (12)(34).$$

$$\rho_4: \begin{array}{cc} (1) & (4) \\ (2) & (3) \end{array} \quad \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 4 & 3 & 2 \end{pmatrix} = (1)(24)(3).$$

2 Cycle notation

Let x_i represent a cycle of length i .

Then, for example, we can represent

- (1) as x_1 ;
- (12) as x_2 ;

- (1234) as x_4 ;
- (13)(24) as x_2^2 ;
- (1)(2)(3)(4) as x_1^4 ;
- (1)(2)(34) as $x_1^2 x_2$.

We can represent the symmetries of a square in cycle notation.

$$\begin{aligned}
 e: & x_1^4 \\
 r: & x_4 \\
 r^2: & x_2^2 \\
 r^3: & x_4 \\
 \rho_1: & x_2^2 \\
 \rho_2: & x_1^2 x_2 \\
 \rho_3: & x_2^2 \\
 \rho_4: & x_1^2 x_2
 \end{aligned}$$

In a colouring problem, each member of a cycle must be coloured the same way, since the elements are mapped onto each other by the symmetry in question.

For example, (13) means $1 \rightarrow 3$ and $3 \rightarrow 1$, so 1 and 3 must be the same colour.

So if there are m colours, each x_i represents a set of elements that can be coloured m different ways.

3 Burnside's Theorem

Theorem. For G a group of permutations of $\{1, 2, \dots, n\}$, the cycle index of G is

$$P(x_1, x_2, \dots, x_n) = \frac{1}{|G|} \sum_{\pi \in G} (\text{cycle representation of } \pi).$$

Then the number of m -colourings of configurations acted upon by G is $P(m, m, \dots, m)$.

3.1 Example

For colouring the vertices of a square, we have

$$\begin{aligned}
 P(x_1, x_2, x_3, x_4) &= \frac{1}{8} (x_1^4 + x_4 + x_2^2 + x_4 + x_2^2 + x_1^2 x_2 + x_2^2 + x_1^2 x_2) \\
 &= \frac{1}{8} (x_1^4 + 2x_4 + 3x_2^2 + 2x_1^2 x_2).
 \end{aligned}$$

We can 2-colour this in

$$P(2, 2, 2, 2) = \frac{1}{8} (2^4 + 2 \times 2 + 3 \times 2^2 + 2 \times 2^2 \times 2) = 6$$

ways.

4 Example

How many ways are there to colour the vertices of a regular pentagon with up to 5 colours?

First we consider the five rotations.

Next we consider the following five reflections.

Collecting the cycle representations together, we have

$$P(x_1, x_2, x_3, x_4, x_5) = \frac{1}{10} (x_1^5 + 4x_5 + 5x_1 x_2^2).$$

Thus we can 5-colour the shape in

$$P(5, 5, 5, 5, 5) = \frac{1}{10} (5^5 + 4 \times 5 + 5 \times 5 \times 5^2) = 377$$

ways.

5 Pólya enumeration

For colouring the vertices of a square like this

we obtained the function

$$P(x_1, x_2, x_3, x_4) = \frac{1}{8} (x_1^4 + 2x_4 + 3x_2^2 + 2x_1^2 x_2).$$

Elements in x_1 (e.g. (1)) can be coloured either

- blue: $1 + b$;
- green: $1 + g$.

So together these can be coloured $(1 + b)(1 + g) = 1 + b + g + bg$ ways.

There is one element in x_1 and we require that it has a colour, therefore its colours can be expressed as $b + g$.

For x_2 (e.g. (12)), we have

- blue: $1 + b + b^2$;
- green: $1 + g + g^2$.

This gives $(1 + b + b^2)(1 + g + g^2) = 1 + g + g^2 + b + bg + bg^2 + b^2 + b^2g + b^2g^2$.

Those terms which represent two elements coloured with the same colour are: $b^2 + g^2$.

In general, x_i can be coloured in $b^i + g^i$ ways.

Now consider

$$\begin{aligned} P(b + g, b^2 + g^2, b^3 + g^3, b^4 + g^4) &= \frac{1}{8} ((b + g)^4 + 2(b^4 + g^4)^2 + 3(b^2 + g^2)^2 + 2(b + g)^2(b^2 + g^2)) \\ &= b^4 + b^3g + 2b^2g^2 + bg^3 + g^4. \end{aligned}$$

These terms generate the 6 ways of colouring the square.

5.1 Example

For colouring the vertices of the regular pentagon we found

$$P(x_1, x_2, x_3, x_4, x_5) = \frac{1}{10} (x_1^5 + 4x_5 + 5x_1x_2^2).$$

Then

$$\begin{aligned} P(b + g, \dots, b^5 + g^5) &= \frac{1}{10} ((b + g)^5 + 4(b^5 + g^5) + 5(b + g)(b^2 + g^2)^2) \\ &= b^5 + b^4g + 2b^3g^2 + 2b^2g^3 + bg^4 + g^5. \end{aligned}$$

These terms generate the 8 ways to 2-colour the regular pentagon.
